

Dr. Smith revealed that this mass of metal had been analyzed under a lens and that there had been identified only 5% of metal generally known on this planet. In this minimum 5% there had been found barium, silicose, magnesium, manganese, copper, nickel, aluminum, vanadium, molybdenum, cobalt, titanium and iron. But, a fact strange at least, no expert of the research department has been able to identify the other 95% of the metal. For them, it is a mystery. It is the unknown.

How does it happen that this object was found in the St. Lawrence River? Mystery.

How is it possible that with the help of the best modern tools, it has not been possible to pierce, cut or dismantle this object? Mystery. It resists everything.

How does it happen that there are found in it pipe entrances, and protuberances of all sorts? Mystery, yet again.

The only conclusion which it is logically possible to apply to the discovery of this "thing" is that it comes from another world ... probably from a flying saucer which disintegrated, and a piece of which happened to fall in the St. Lawrence River.

What is the "thing"? Only the future and the scientists can tell us, in a more or less distant future.
